

Windows of Developmental Sensitivity to Social Media

Professor Andrew Przybylski

Dr. Amy Orben

Rates of reported adolescent mental health conditions have increased over the last decade (NHS Digital, 2020)

In the UK today, an estimated 5 children in every classroom has a mental health condition (Young Minds, 2021)

Half of all mental health conditions start by 14 years of age (Kessler et al. 2007)

Data taken from the US National Survey on Drug Use and Health, Table 11.2b

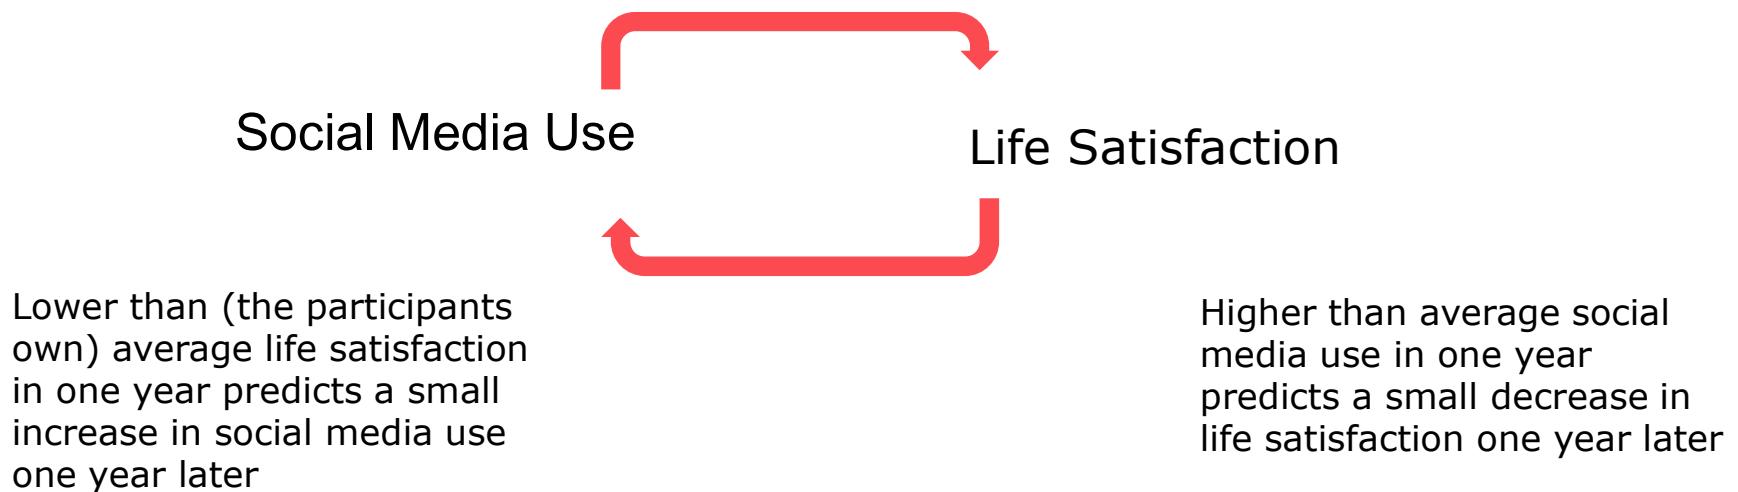

Previous Work

- Correlation between adolescent mental health and social media use is very small and negative (Odgers and Jensen 2020; Orben 2020; Hancock et al. 2019)
- Mixed results in both observational and experimental work (Allcott et al. 2019; Aalbers et al. 2018; Orben and Przybylski 2019a, 2019b)

Directional Links

12,672 adolescents (10-15 years old; Understanding Society Dataset)

Orben, Amy, Tobias Dienlin, and Andrew K Przybylski (2019, PNAS)

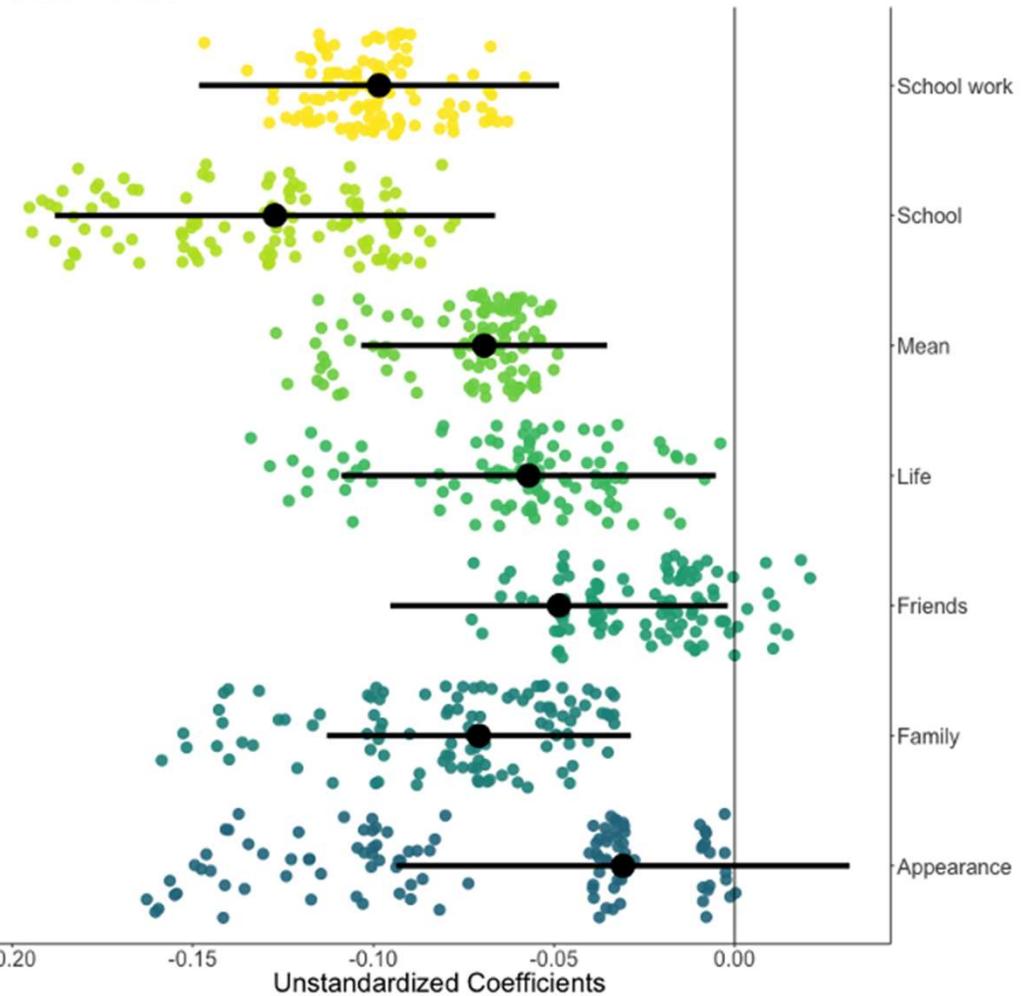

Examining gender differences

12,672 adolescents (10-15 years old;
7 annual waves questionnaire data, UK)

2. Social Media Use \rightarrow Life Satisfaction

Gender: Female

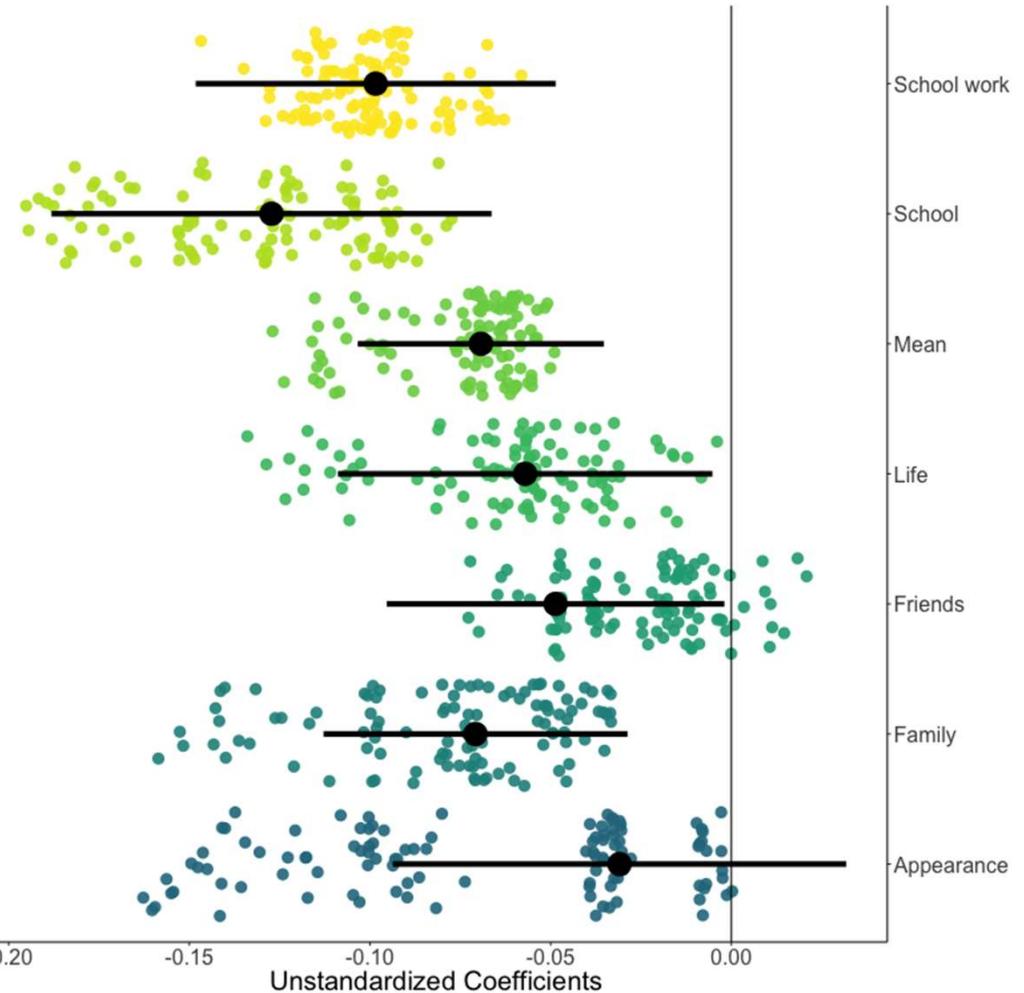

Orben, Dienlin and Przybylski, 2019, PNAS

Examining gender differences

12,672 adolescents (10-15 years old;
7 annual waves questionnaire data, UK)

2. Social Media Use -> Life Satisfaction Gender: Female

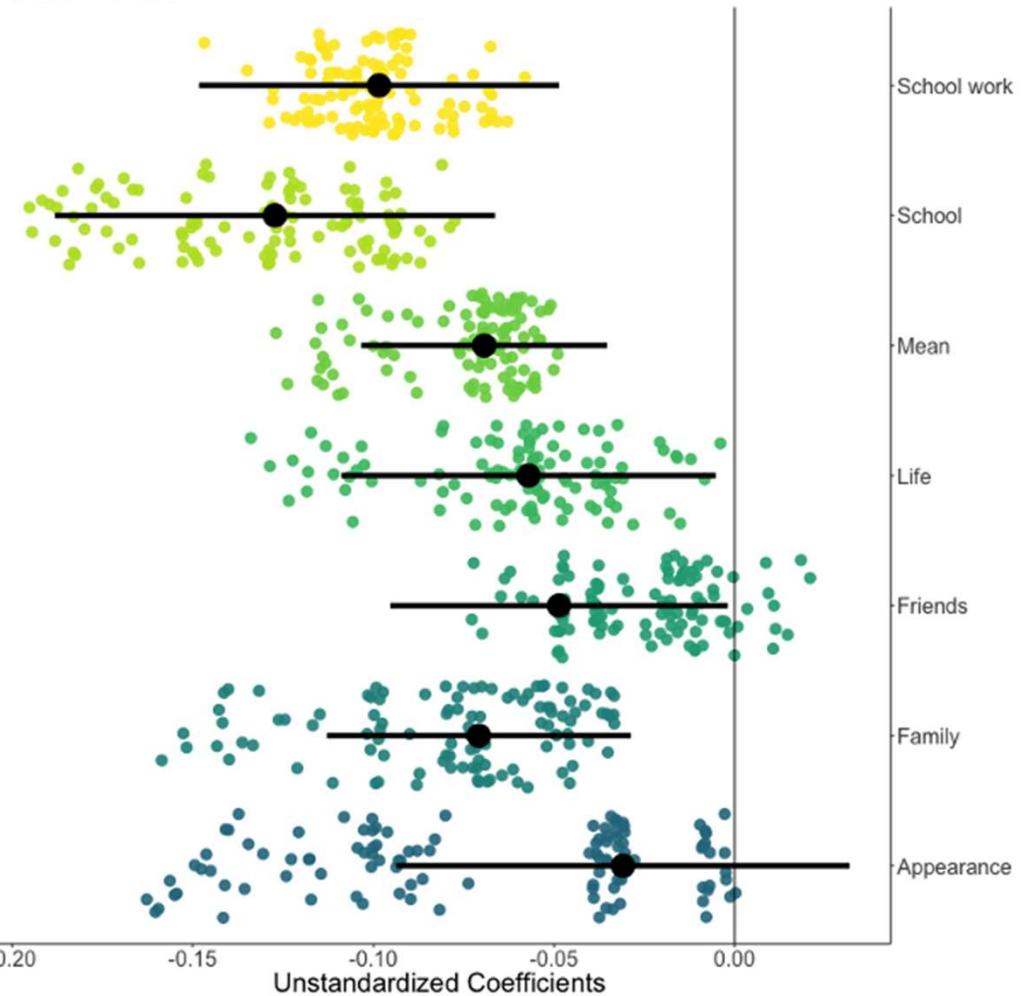

Orben, Dienlin and Przybylski, 2019, PNAS

Examining gender differences

12,672 adolescents (10-15 years old;
7 annual waves questionnaire data, UK)

2. Social Media Use \rightarrow Life Satisfaction

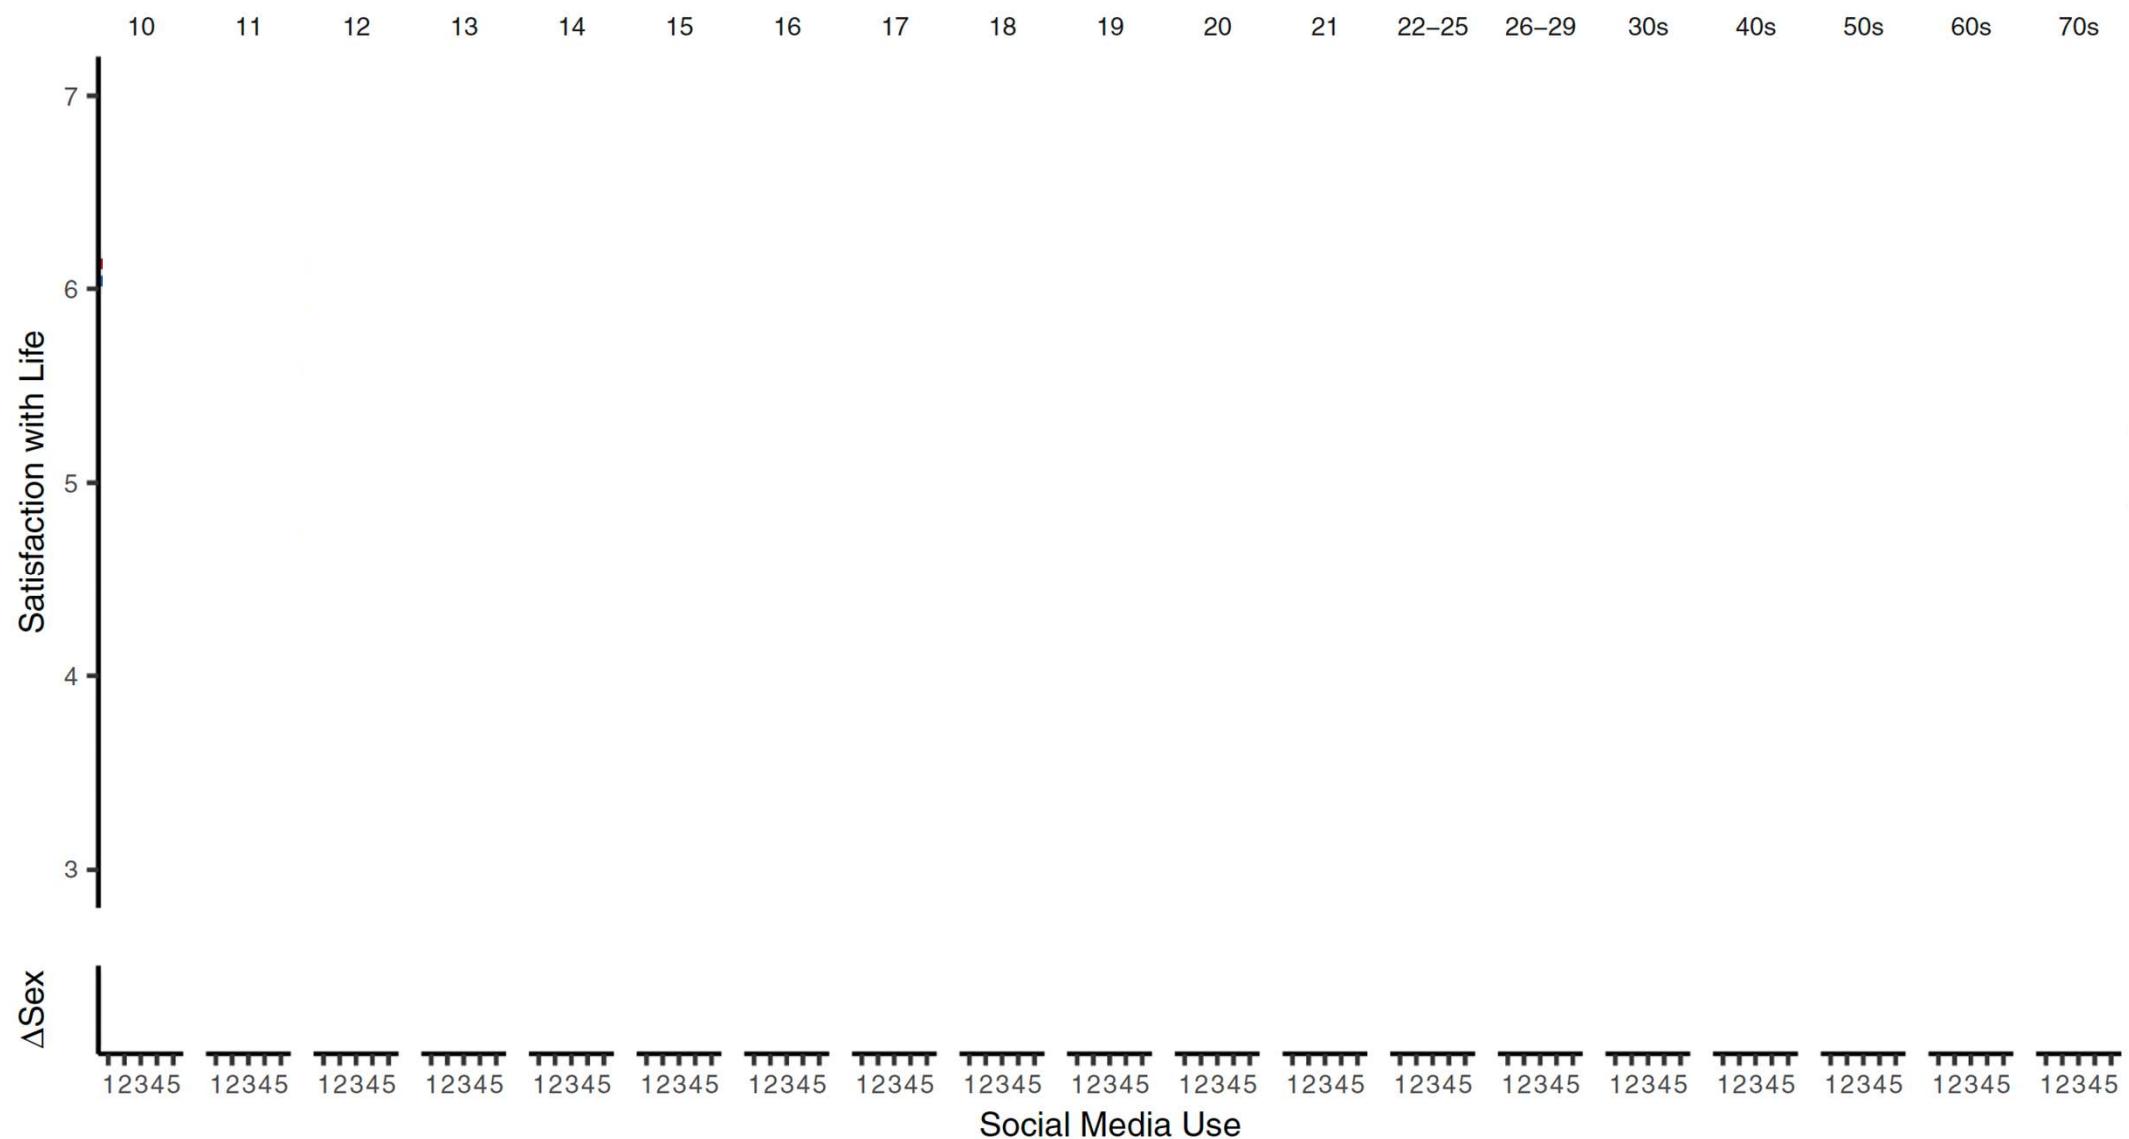

Gender: Female

Orben, Dienlin and Przybylski, 2019, PNAS

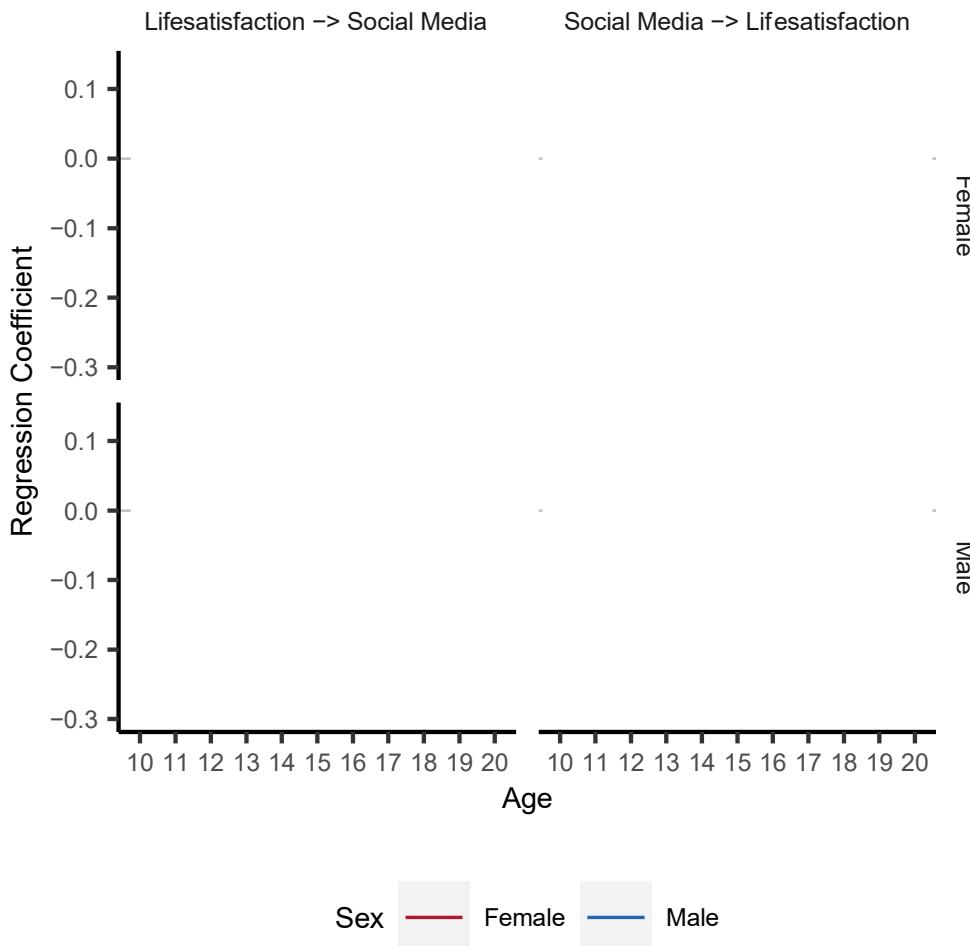

What is new in this work?

1. Inclusion of **larger age range**: cross-sectional data across the lifespan & longitudinal data for ages 10-21 years
2. Two datasets of over **84,000 UK participants**, with one dataset (17,409 participants) being collected over 7 annual waves
3. Pioneering a developmental approach: our statistical modelling allowed the bidirectional links between social media use and life satisfaction to **vary across age**

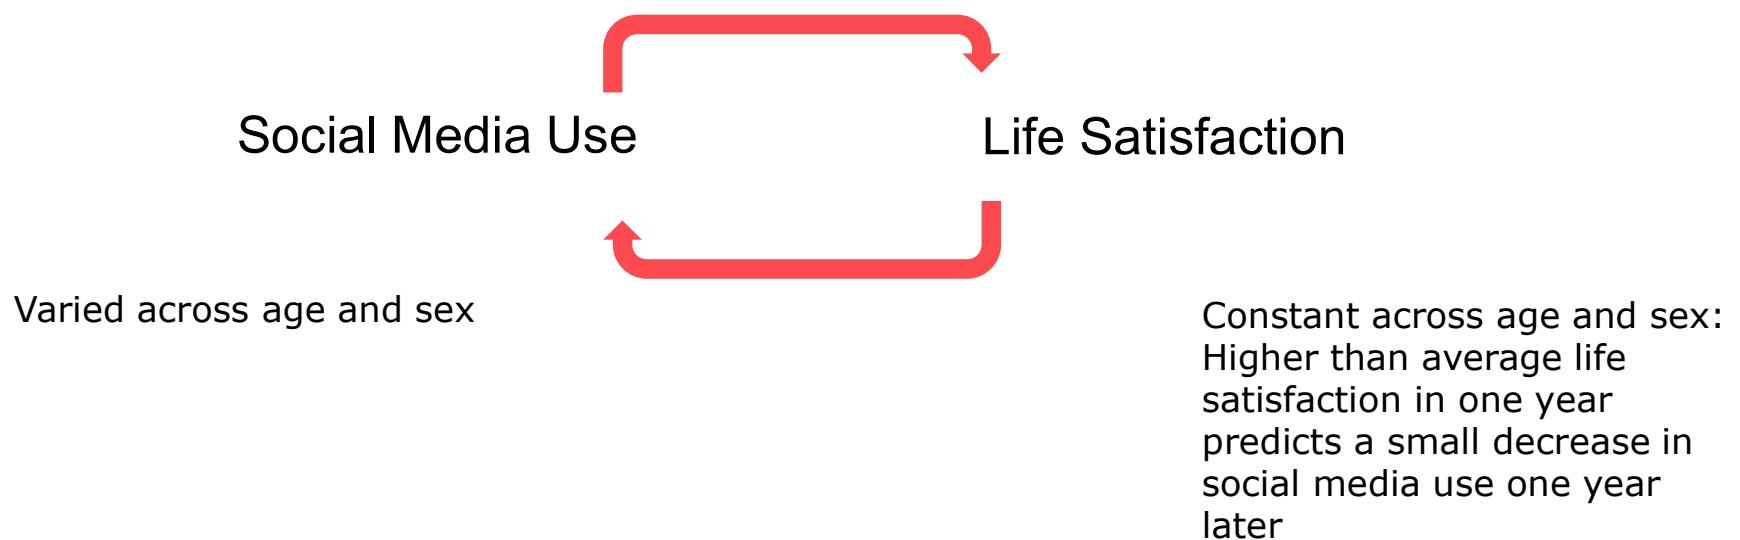

72,287 UK participants between the age of 10 and 80 years

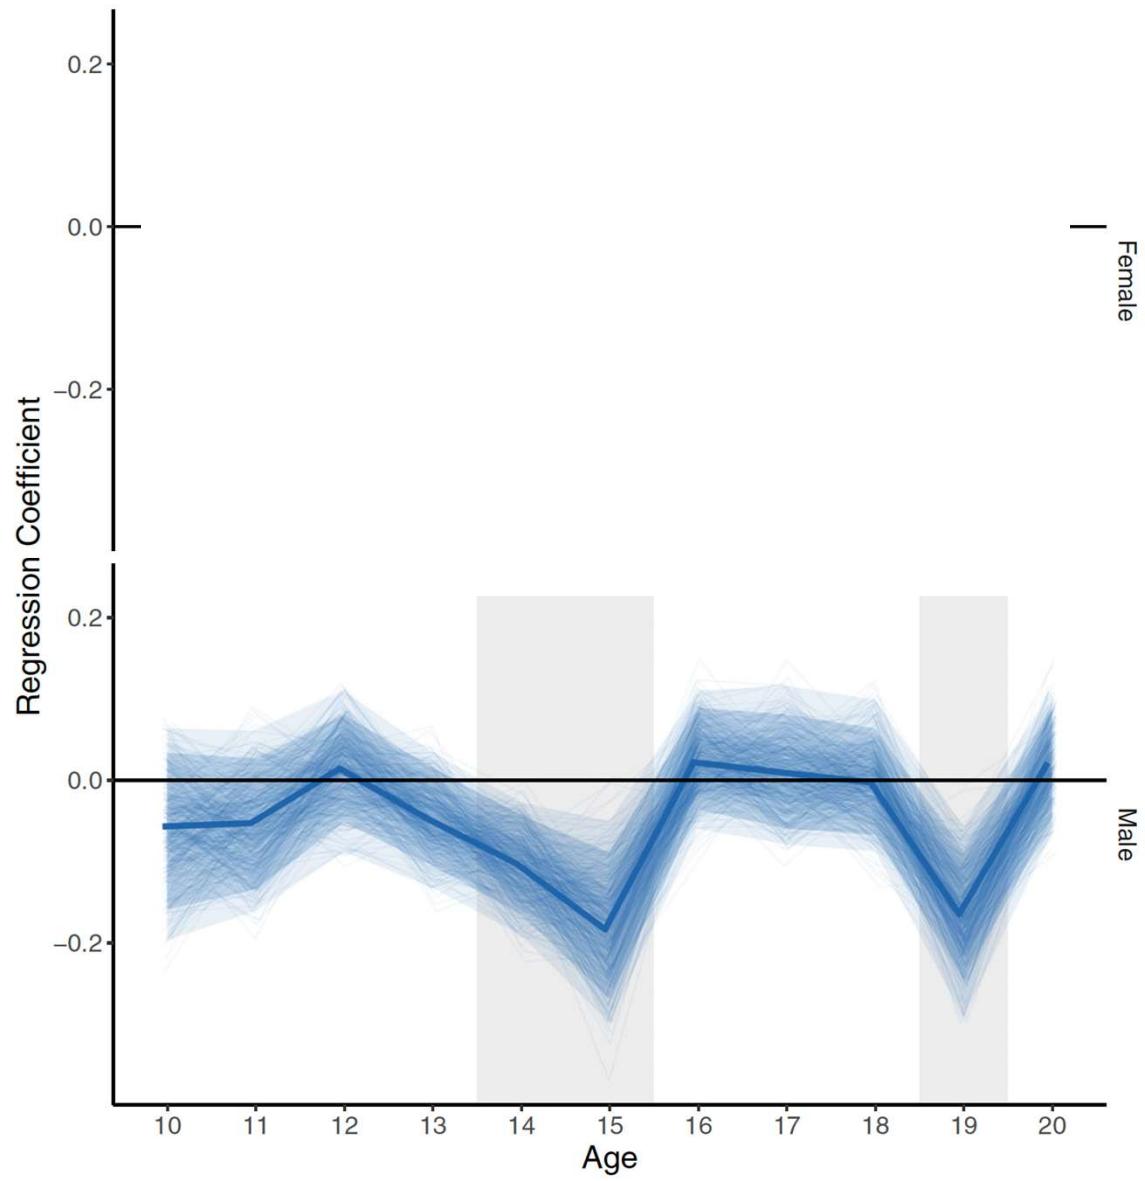

$\chi^2 (434) = 1216.29$, $p < 0.001$,
RMSEA = 0.014, [0.013,
0.015], CFI = 0.944, SRMR =
0.072; Full Informational
Maximum Likelihood
estimation; two-tailed test).

Longitudinal Results

17,409 adolescents (10-21 years old; Understanding Society Dataset)

Conclusions

- There is evidence of **bidirectional links** with social media use predicting small decreases in life satisfaction one year later and vice versa
- Importantly, we find that there are **certain ages** (which differ between sexes) when social media more substantially predicts life satisfaction
- Follow up research from my group is investigating the practical significance of these associations **using Innovation Panel data**.

Thank You
